MO8921
High Frequency, -55°C to +125°C Oscillator

Features

- Frequencies between 119.342001 MHz and 137 MHz accurate to 6 decimal places
- Operating temperature from -55°C to +125°C
- Supply voltage of +1.8V or +2.5V to +3.3V
- Excellent total frequency stability as low as ±20 ppm
- Low power consumption of +4.9 mA typical at 20 MHz, +1.8V
- LVCMOS/LVTTL compatible output
- Industry-standard packages: 2.0 x 1.6, 2.5 x 2.0, 3.2 x 2.5, 5.0 x 3.2, 7.0 x 5.0 mm x mm
- Instant samples with Time Machine II and field programmable oscillators
- RoHS and REACH compliant, Pb-free, Halogen-free and Antimony-free

Applications

- Ruggedized equipment in harsh operating environment

Notes:

1. In OE or $\overline{ST}$ mode, a pull-up resistor of 10kΩ or less is recommended if pin 1 is not externally driven. If pin 1 needs to be left floating, use the NC option.
2. A capacitor of value 0.1 µF or higher between Vdd and GND is required.

Table 3. Absolute Maximum Limits

Attempted operation outside the absolute maximum ratings of the part may cause permanent damage to the part. Actual performance of the IC is only guaranteed within the operational specifications, not at absolute maximum ratings.

Parameter	Min.	Max.	Unit
Storage Temperature	-65	+150	°C
Vdd	-0.5	+4.0	V
Electrostatic Discharge	–	+2000	V
Soldering Temperature (follow standard Pb free soldering guidelines)	–	+260	°C
Junction Temperature[3]	–	+150	°C

Note:

3. Exceeding this temperature for extended period of time may damage the device.

Programmable Drive Strength

The MO8921 includes a programmable drive strength feature to provide a simple, flexible tool to optimize the clock rise/fall time for specific applications. Benefits from the programmable drive strength feature are:

- Improves system radiated electromagnetic interference (EMI) by slowing down the clock rise/fall time
- Improves the downstream clock receiver's (RX) jitter by decreasing (speeding up) the clock rise/fall time.
- Ability to drive large capacitive loads while maintaining full swing with sharp edge rates.

For more detailed information about rise/fall time control and drive strength selection, contact KDS.

EMI Reduction by Slowing Rise/Fall Time

Figure 16 shows the harmonic power reduction as the rise/fall times are increased (slowed down). The rise/fall times are expressed as a ratio of the clock period. For the ratio of 0.05, the signal is very close to a square wave. For the ratio of 0.45, the rise/fall times are very close to near-triangular waveform. These results, for example, show that the 11th clock harmonic can be reduced by 35 dB if the rise/fall edge is increased from 5% of the period to 45% of the period.

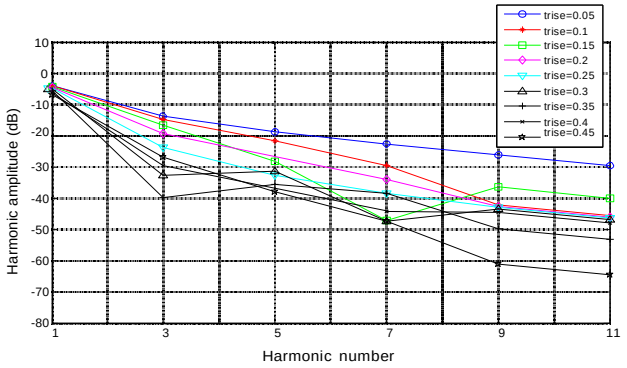

Figure 16. Harmonic EMI reduction as a Function of Slower Rise/Fall Time

Jitter Reduction with Faster Rise/Fall Time

Power supply noise can be a source of jitter for the downstream chipset. One way to reduce this jitter is to speed up the rise/fall time of the input clock. Some chipsets may also require faster rise/fall time in order to reduce their sensitivity to this type of jitter. Refer to the Rise/Fall Time Tables (Table 7 to Table 11) to determine the proper drive strength.

High Output Load Capability

The rise/fall time of the input clock varies as a function of the actual capacitive load the clock drives. At any given drive strength, the rise/fall time becomes slower as the output load increases. As an example, for a +3.3V MO8921 device with default drive strength setting, the typical rise/fall time is 0.46ns for 5 pF output load. The typical rise/fall time slows down to 1ns when the output load increases to 15 pF. One can choose to speed up the rise/fall time to 0.72ns by then increasing the drive strength setting on the MO8921 to "F".

The MO8921 can support up to 30 pF or higher in maximum capacitive loads with up to 3 additonal drive strength settings. Refer to the Rise/Tall Time Tables (Table 7 to 11) to determine the proper drive strength for the desired combination of output load vs. rise/fall time

MO8921 Drive Strength Selection

Tables 7 through 11 define the rise/fall time for a given capacitive load and supply voltage.

1. Select the table that matches the MO8921 nominal supply voltage (+1.8V, +2.5V, +2.8V, +3.0V, +3.3V).
2. Select the capacitive load column that matches the application requirement (5 pF to 30 pF)
3. Under the capacitive load column, select the desired rise/fall times.
4. The left-most column represents the part number code for the corresponding drive strength.
5. Add the drive strength code to the part number for ordering purposes.

Calculating Maximum Frequency

Based on the rise and fall time data given in Tables 7 through 11, the maximum frequency the oscillator can operate with guaranteed full swing of the output voltage over temperature as follows:

$$\text{Max Frequency} = \frac{1}{5 \times \text{Trf\_20/80}}$$

where Trf_20/80 is the typical value for 20%-80% rise/fall time.

Example 1

Calculate f_{MAX} for the following condition:

- Vdd = +3.3V (Table 11)
- Capacitive Load: 30 pF
- Desired Tr/f time = 1.46 ns (rise/fall time part number code = E)

Part number for the above example:

MO8921MG4-C**U**H-33E0-0136986300

Pin 1 Configuration Options (OE, $\overline{ST}$, or NC)

Pin 1 of the MO8921 can be factory-programmed to support three modes: Output Enable (OE), standby ($\overline{ST}$) or No Connect (NC). These modes can also be programmed with the Time Machine using field programmable devices.

Output Enable (OE) Mode

In the OE mode, applying logic Low to the OE pin only disables the output driver and puts it in Hi-Z mode. The core of the device continues to operate normally. Power consumption is reduced due to the inactivity of the output. When the OE pin is pulled High, the output is typically enabled in <1µs.

Standby ($\overline{ST}$) Mode

In the $\overline{ST}$ mode, a device enters into the standby mode when Pin 1 pulled Low. All internal circuits of the device are turned off. The current is reduced to a standby current, typically in the range of a few µA. When $\overline{ST}$ is pulled High, the device goes through the "resume" process, which can take up to 5 ms.

No Connect (NC) Mode

In the NC mode, the device always operates in its normal mode and output the specified frequency regardless of the logic level on pin 1.

Table 12 below summarizes the key relevant parameters in the operation of the device in OE, $\overline{ST}$, or NC mode.

Table 12. OE vs. $\overline{ST}$ vs. NC

	OE	$\overline{ST}$	NC
Active current 125 MHz (max, +1.8V)	+6.0 mA	+6.0 mA	+6.0 mA
OE disable current (max. +1.8V)	+4.5 mA	N/A	N/A
Standby current (typical +1.8V)	N/A	+0.6 µA	N/A
OE enable time at 125MHz (max)	130 ns	N/A	N/A
Resume time from standby (max, all frequency)	N/A	5.0 ms	N/A
Output driver in OE disable/standby mode	High Z	weak pull-down	N/A

Output on Startup and Resume

The MO8921 comes with gated output. Its clock output is accurate to the rated frequency stability within the first pulse from initial device startup or resume from the standby mode.

In addition, the MO8921 has no runt, no glitch output during startup or resume as shown in the waveform captures in Figure 17 and Figure 18.

Instant Samples with Time Machine and Field Programmable Oscillators

KDS supports a field programmable version of the MO8921 high temperature oscillator for fast prototyping and real time customization of features. The field programmable devices (FP devices) are available for all five standard MO8921 package sizes and can be configured to one's exact specification using the Time Machine II, an USB powered MEMS oscillator programmer.

Customizable Features of the MO8921 FP Devices Include

- Frequencies between 119.3420001 – 137 MHz
- Four frequency stability options, ±20 ppm, ±25 ppm, ±30 ppm, ±50 ppm
- Six supply voltage options, +1.8V, + 2.5V, +2.8V, +3.0V, +3.3V and +2.25 to +3.63V continuous
- Output drive strength

For more information regarding KDS's field programmable solutions, contact KDS.

MO8921 is factory-programmed per customer ordering codes for volume delivery.
